In computer science, the subset sum problem is an important decision problem in complexity theory and cryptography.There are several equivalent formulations of the problem. One of them is: given a set (or multiset) of integers, is there a non-empty subset whose sum is zero?For example, given the set {â˜, â˜, â˜,,}, the answer is yes because the subset {â˜, â˜,} sums to zero.

Box and Cox (1964) developed the transformation. Estimation of any Box-Cox parameters is by maximum likelihood. Box and Cox (1964) offered an example in which the data had the form of survival times but the underlying biological structure was of hazard rates, and the transformation identified this.

The Potts model is a binary penalising function with a single tunable variable. This value controls how much smoothing is applied. The linear and quadratic models have an extra parameter K. K is a truncation value that caps the maximum penalty.
